Case Report

A Rare Case of Perforated Meckel’s Diverticulum Presenting as a Gastrointestinal Stromal Tumor

Selim Sozen MD1, Ömer Tuna MD1

Abstract

Meckel’s diverticulum is located on the antimesentric border of the ileum, approximately 45 to 60 cm proximal to the ileocecal valve, and results from incomplete closure of the omphalomesentric or viteline duct. Common complications presenting in adults include bleeding, obstruction, diverticulitis, and perforation. Tumors within Meckel’s diverticulum are a rare, but recognized complication.

A 62-year-old woman presented with peri-umbilical pain that had localized to the right iliac fossa. On examination, she was tender in the right iliac fossa, with localized peritonism. At surgery, a perforated Meckel’s diverticulum was found that was associated with free intra-abdominal fluid and hemorrhage. A 25 mm nodule was found at the apex of Meckel’s diverticulum. We resected 100 mm of the small bowel and a primary anastomosis was performed. Histopathological examination of the resected lesion revealed a mesenchymal tumor categorized as a gastrointestinal stromal tumor (GISTs).

GISTs arising from Meckel’s diverticulum are an extremely rare, but recognized complication. Surgery is considered the standard treatment for non-metastatic GISTs with en bloc resection and clear margins.

Keywords: Complications, gastrointestinal stromal tumor, Meckel’s diverticulum

Introduction

Meckel’s diverticulum is the most commonly encountered congenital anomaly of the small intestine, occurring in approximately 1/100 individuals. It is a remnant of the omphalomesentric or viteline duct. Common complications presenting in adults include bleeding, obstruction, diverticulitis, and perforation. Tumors within Meckel’s diverticulum are a rare but recognized complication. Meckel’s diverticulum is located on the antimesentric border of the ileum, approximately 45 to 60 cm proximal to the ileocecal valve, and results from incomplete closure of the omphalomesentric or viteline duct. Common complications presenting in adults include bleeding, obstruction, diverticulitis, and perforation. Tumors within Meckel’s diverticulum are a rare but recognized complication.

A 62-year-old woman presented with peri-umbilical pain that had localized to the right iliac fossa. On examination, she was tender in the right iliac fossa, with localized peritonism. At surgery, a perforated Meckel’s diverticulum was found that was associated with free intra-abdominal fluid and hemorrhage. A 25 mm nodule was found at the apex of Meckel’s diverticulum. We resected 100 mm of the small bowel and a primary anastomosis was performed. Histopathological examination of the resected lesion revealed a mesenchymal tumor categorized as a gastrointestinal stromal tumor (GISTs).

Case Report

A 62-year-old woman presented with peri-umbilical pain that had localized to the right iliac fossa. On examination, she was tender in the right iliac fossa, with localized peritonism. Hematologic tests showed decreased hematocrit (Ht: 22%) and a platelet (PLT) count of 114000/mL. Her Hiser white cell count was 15.2 x 10^9 (neutrophils: 12.1 x 10^9). On physical examination, there was abdominal tenderness, rebound, and increased bowel sounds in all quadrants. Plain abdominal X-rays were first obtained when the patient had acute symptoms, which revealed air-fluid levels that suggested intestinal obstruction (Figure 1). A palpable mass in the right lower quadrant was present. The patient underwent surgery with a diagnosis of parastomal appendicitis. A McBurney incision in the abdomen was made; the appendix was normal. During surgery, a perforated Meckel’s diverticulum was found, which was associated with free intra-abdominal fluid and hemorrhage (Figure 2). A 25 mm nodule was found at the apex of Meckel’s diverticulum. The perforation of the diverticulum was also not associated with the tumor nodule. At the subsequent laparotomy, 100 mm of small bowel was resected and primary anastomosis performed. Histology confirmed a Meckel’s diverticulum with a 12 mm area of perforation. The histopathological examination of the resected lesion revealed a mesenchymal tumor, which was categorized as a GIST tumor. The stromal tumor demonstrated whirling sheets of spindle cells with a moderate level of pleomorphism and mitotic activity (6 – 7 mitoses/50 HPF; H&E stain). No necrosis was observed. Immunohistochemical staining for CD117, a-smooth-muscle actin (SMA), and S-100 protein was positive, whereas staining for desmin and CD34 was negative (Figure 3). The labeling index for MIB-1, determined by counting positively stained nuclei, was about 5%. The postoperative period was unremarkable and she was discharged in good general condition.

Discussion

Meckel’s diverticulum is the most commonly encountered congenital anomaly of the small intestine, occurring in approximately 1/100 individuals.
GISTs, which arise primarily in the gut wall, are uncommon mesenchymal, malignant, or potentially malignant tumors affecting the gastrointestinal tract. GISTs are the most common non-epithelial tumors of the digestive tract, accounting for only 1% of all gastrointestinal malignancies. Primary GISTs may occur anywhere along the gastrointestinal tract from the esophagus to the anus. The most frequent site is the stomach (55%), followed by the duodenum and small intestine (30%), esophagus (5%), rectum (5%), colon (2%), and rare other locations. The incidence of tumors within Meckel’s diverticulum is 0.5% to 3.2%. Most are commonly benign tumors such as leiomyomas, angiomas, and lipomas. Malignant neoplasms include adenocarcinoma (which commonly originate from the gastric mucosa), carcinoma, carcinoid tumor, and GISTs.

The most common presentation of GISTs is acute or chronic gastrointestinal bleeding. They often present with nausea, vomiting, abdominal pain, metastatic disease, and bowel obstruction. In our case, the patient presented with bowel obstruction and perforation. In a large series of 1476 cases at the Mayo Clinic, Park et al. have reported the most common presentations of symptomatic Meckel’s diverticulum in adults to be bleeding (38%), obstruction (34%), diverticulitis (28%) and perforation (10%). GISTs arise from the interstitial cells of Cajal, the pacemaker cells of the gastrointestinal tract. GISTs strongly expresses the KIT (CD 117) protein and may harbor mutations of the type III tyrosine kinase receptor gene (either KIT or PDGFRA). For many patients, detection of GISTs may be an incidental finding during evaluation of nonspecific symptoms. Symptoms tend to arise only when tumors reach a large size or are in a critical anatomic location. Most symptomatic patients present with tumors larger than 5 cm in maximal dimension. Symptoms at presentation may include abdominal pain, abdominal mass, nausea, vomiting, anorexia, and weight loss. There are little prognostic data regarding GISTs and current prognostic indicators are based on consensus guidelines. The most important adverse factors are thought to be a tumor diameter of greater than 5 cm and a high mitotic count exceeding 5 mitotic figures per 50 high powered fields on light microscopy. Other suggested factors indicative of poor prognosis include tumor perforation, tumor necrosis, high cellularity, and marked pleomorphism.

Surgery is considered the standard treatment for non-metastatic
GISTs with en bloc resection and clear margins. The treatment of choice is the complete resection of the tumour. The surgeon’s approach in an actual case depends on factors such as: the exact anatomical site of the GISTs, the characteristics of the individual patient’s particular situation, and the specific location of the tumour relative to the blood supply of the involved organ. There is little evidence to support local/regional lymphadenectomy as GISTs rarely metastasize to lymph nodes. Targeted therapy with imatinib, a KIT tyrosine kinase inhibitor, is considered the standard treatment for metastatic GISTs. In our case, the outcome has shown that the location is very important in determining the prognosis. Patients with a small bowel localization do worse than those with stomach GISTs as reported by DeMatteo et al. In a case of a MD (Meckel diverticulum) localization, treatment with imatinib mesylate has been reported by Khoury et al., but the impact on the clinical behavior of the disease has not been described. The case reported by us has a low risk of recurrence based on characteristics of a maximum diameter of 2.5 cm, a low mitotic count of less than one mitotic figure in 10 × 40 high powered fields, and no evidence of necrosis. Importantly, the perforation of the diverticulum was also not associated with the tumor nodule.

Conclusion

GISTs arising from Meckel’s diverticulum are an extremely rare but recognized complication. Surgery is considered the standard treatment for non-metastatic GISTs with en bloc resection and clear margins.
